INVESTOR IN PEOPLE

The Patent Office
Concept House
Cardiff Road
Newport
South Wales
NP10 8QQ

I, the undersigned, being an officer duly authorised in accordance with Section 74(1) and (4) of the Deregulation & Contracting Out Act 1994, to sign and issue certificates on behalf of the Comptroller-General, hereby certify that annexed hereto is a true copy of the documents as originally filed in connection with the patent application identified therein.

In accordance with the Patents (Companies Re-registration) Rules 1982, if a company named in this certificate and any accompanying documents has re-registered under the Companies Act 1980 with the same name as that with which it was registered immediately before re-registration save for the substitution as, or inclusion as, the last part of the name of the words "public limited company" or their equivalents in Welsh, references to the name of the company in this certificate and any accompanying documents shall be treated as references to the name with which it is so re-registered.

In accordance with the rules, the words "public limited company" may be replaced by p.l.c., plc, P.L.C. or PLC.

Re-registration under the Companies Act does not constitute a new legal entity but merely subjects the company to certain additional company law rules.

Warning

After an application for a patent has been filed, the Comptroller of the Patent Office will consider whether publication or communication of the invention should be prohibited or restricted under Section 22 of the Patents Act 1977. You will be informed if it is necessary to prohibit or restrict your invention in this way. Furthermore, if you live in the United Kingdom, Section 23 of the Patents Act 1977 stops you from applying for a patent abroad without first getting written permission from the Patent Office unless an application has been filed at least 6 weeks beforehand in the United Kingdom for a patent for the same invention and either no direction prohibiting publication or communication has been given, or any such direction has been revoked.

Notes

- If you need help to fill in this form or you have any questions, please contact the Patent Office on 0645 500505.
- Write your answers in capital letters using black ink or you may type them.
- If there is not enough space for all the relevant details on any part of this form, please continue on a separate sheet of paper and write "see continuation sheet" in the relevant part(s). Any continuation sheet should be attached to this form.
- If you have answered "Yes" Patents Form 7/77 will need to be filed.
- Once you have filled in the form you must remember to sign and date it.

DESCRIPTION

IMPROVEMENTS IN OR RELATING TO WIRELESS TERMINALS

5 The present invention relates to improvements in or relating to wireless terminals, particularly, but not exclusively, to wireless terminals operating in accordance with protocols including frequency division duplex (FDD) systems, such as GSM, DCS and UMTS, having separate transmit and receive frequency bands.

10 Typically cellular telephones have a common antenna for receiving and transmitting signals within a relatively wide bandwidth. Various antenna arrangements are known in the art which have a wide enough bandwidth to cover both the transmitter and receiver frequencies used the FDD system.

15 US Patent Specification 5,659,886 discloses in its preamble that in conventional mobile units for digital radio communication, both the receiver and transmitter are connected to a common receive/transmit antenna via a transmitting passband filter and a receiving passband filter. These filters may be fabricated as dielectric filters or acoustic wave filters. Since such
20 components are difficult to fabricate as integrated circuits and also they are relatively bulky, this patent specification proposes that the transmitting bandpass filter be replaced by an isolator in order to reduce bulk. In the specific examples described, the common antenna comprises an external whip antenna. Isolators are themselves are regarded as being inefficient devices
25 because they can dissipate power reflected from the antenna.

Wireless terminals, such as mobile phone handsets, sometimes have an internal antenna, such as a Planar Inverted-F Antenna (PIFA) or similar. Such antennas are small (relative to a wavelength) and therefore, owing to the fundamental limits of small antennas, narrow band. However, cellular radio
30 communication systems such as UMTS require a PIFA to have a fractional bandwidth of 13.3%. To achieve such a bandwidth from a PIFA for example requires a considerable volume, there being a direct relationship between the

bandwidth of an antenna and its volume, but such a volume is not readily available with the current trends towards small handsets. Hence, because of the limits referred to above, it is not feasible to achieve efficient wide band radiation from small antennas in present-day wireless terminals.

5 It is an object of the present invention to cover wanted frequency bands⁹ lying within a relatively wide bandwidth from a relatively small volume common receive/transmit antenna.

10 According to one aspect of the present invention there is provided a wireless terminal for use in the transmitting and receiving frequency bands of a frequency duplex system, comprising transmitting and receiving stages and signal propagating means coupled to the transmitting and receiving stages, wherein the signal propagating means comprises an antenna structure having sufficient bandwidth to cover the larger one of the transmitting and receiving
15 frequency bands, a receiving filter and a transmitting filter coupled by respective feeds to the antenna structure.

According to a second aspect of the present invention there is provided a module for use in a wireless terminal operable in the transmitting and receiving frequency bands of a frequency duplex system, comprising signal
20 propagating means including an antenna structure having sufficient bandwidth to cover the larger one of the transmitting and receiving frequency bands, a receiving filter and a transmitting filter coupled by respective feeds to the antenna structure and having terminals for connection to the RF stages the wireless terminal.

25 The present invention is based on recognition of the fact that filters can be used to make a narrow band antenna structure reusable at different frequencies lying in a pass band bridging the transmitter and receiver pass bands of a FDD system.

30 In an embodiment of the invention the antenna structure comprises a PIFA. The PIFA may include two differential slots which separate the PIFA into a central element and two outer elements which are interconnected at one end. A free end of the central element is connected to a ground plane and the

free ends of the two outer elements are connected respectively to the transmitting and receiving filters.

The filters may be solid state filters such as Bulk Acoustic Wave (BAW) and Surface Acoustic Wave (SAW) filters.

5

The present invention will now be described, by way of example, with reference to the accompanying drawings, wherein:

Figure 1 is a block schematic diagram of an embodiment of a wireless terminal made in accordance with the present invention,

10 Figure 2 is a diagram of a circuit board having a PIFA and transmitting and receiving filters,

Figure 3 is a diagram illustrating the radiating (or common) and balanced (or differential) modes of PIFA,

15 Figure 4 is a diagram of the antenna structure connected respectively to BAW transmitter and receiver filters, and

Figure 5 is the S_{11} response of the antenna structure and BAW filters.

In the drawings the same reference numerals have been used to indicate corresponding features.

20 Referring to Figure 1, the transceiver comprises a transmitter section Tx including a signal input terminal 10 coupled to an input signal processing stage 12. The stage 12 is coupled to a modulator 14 which provides a modulated signal to a frequency up-converter comprising a multiplier 16 to which a signal generator 18, such as a frequency synthesiser, is also connected. The
25 frequency up-converted signal is coupled to a signal propagating structure 24 by way of a power amplifier 20, a transmitter filter 22 and a matching/frequency tuning network 23.

A receiver section Rx of the transceiver comprises a low noise amplifier 28 coupled to the signal propagating structure 24, by way of a
30 matching/frequency tuning network 25 and a receiver filter 26. An output of the low noise amplifier 28 is coupled to a frequency down-converter comprising a multiplier 30 and a signal generator 32, such as a frequency synthesiser. The

frequency down-converted signal is demodulated in a demodulator 34 and its output is applied to a signal processing stage 36 which provides an output signal on a terminal 38. The operation of the transceiver is controlled by a processor 40.

5 Referring to Figure 2, a printed circuit board PCB has components (not shown) on one side and a ground plane GP on the reverse side. A PIFA 24 is ~~mounted on, or carried by, the PCB. The PIFA can be implemented in several~~
~~alternative ways, for example as a preformed metal plate carried by the PCB~~
using posts of an insulating material, as a pre-etched piece of printed circuit
10 board carried by the PCB, as a block of insulating material having the PIFA formed by selectively etching a conductive layer provided on the insulating material or by selectively printing a conductive layer on the insulating block or as an antenna on the cell phone case. For use at UMTS frequencies, the dimensions of the PIFA 24 are length (dimension "a") 30mm, height
15 (dimension "b") 10 mm and depth (dimension "c") 4mm. These dimensions enable the PIFA 24 to have sufficient bandwidth to cover the larger of the FDD UMTS bands. The bandwidth is substantially 3.1%. This is more than a factor of 4 less than the bandwidth required to cover the entire UMTS band (approximately 13.3%). Nominally the PIFA 24 is resonant between the
20 transmit and receive bands.

The PIFA 24 has two differential slots 42, 44 extending lengthwise for part of the distance from one edge to the other. The result is analogous to a comb having three prongs or elements PR1, PR2 and PR3 interconnected at one of their ends and free at the other of their ends. The middle element PR2
25 is connected by a common shorting pin 46 to the ground plane GP of the PCB. The element PR1 is coupled by a pin 48 to the output of the transmitter filter 22 (Figure 1) and the element PR3 is coupled by a pin 50 to the input of the receiver filter 26 (Figure 1).

The differential slots 42, 44 can also be used to tune the resonant
30 frequency of the antenna. Asymmetric slots, that is, slots of different lengths and/or different shapes, will give different resonant frequencies for the two feeds, viz. the pins 48, 50.

The differential slots are not essential but without them there is a potential problem of the inductance in the coupling to the filter feeding the shorting pin 46. The slots increase the differential mode reactance and facilitates isolation of the unused port, that is, the receiver port in the transmit mode and visa-versa in the receive mode. This is illustrated in Figure 3 in which the drawing shows on the left an embodiment of the PIFA 24 with the element PF2 shorted to ground and a signal source S1 coupled to the element PR1. An arrow 52 indicates that this feed arrangement constitutes a differential port. The PIFA 24 connected in this way can be represented as being equivalent to the combination of a radiating (or common) mode 24R and a balanced (or differential) mode 24B. In the radiating mode 24R, in-phase signal sources S2 and S3 are coupled to the elements PR1 and PR2, respectively, and the PIFA appears as a single one-piece antenna. In the case of the balanced mode 24B, anti-phase sources S4 and S5 are coupled to the elements PR1 and PR2, respectively, so that current flows along PR1 to PR2 as shown by the arrows 54, 56 and a field exists across the slot 42. In this mode the differential mode reactance is increased and it is easier to isolate the unused port by tuning the filter to present a reflective termination, for example an open or short circuit to the antenna.

Referring to Figure 4, the transmitter filter 22 comprises a 4-element, unbalanced, BAW ladder filter coupled to the antenna element PR1 by way of the matching/frequency tuning network 23. This type of filter allows an unbalanced input and output which is generally required for a transmitter. A source impedance represented by a 50 ohm impedance 60 is coupled by a 2nH inductor 62 to the input of the filter 22. A 6nH inductor 64 couples an output of the filter 22 to the antenna element PR1. The inductors 62 and 64 serve for tuning purposes and the value of the inductor 64 is optimised such that it also reduces the resonant frequency of the PIFA 24 to that required for the transmitter frequency band. Additionally, it is arranged such that it presents an approximate short circuit in conjunction with the BAW filter's output static capacitance (not shown) at the receiver frequency.

The receiver filter 24 comprises a balanced, BAW lattice type of filter having a balanced input for connection to a 50 ohm source impedance 70 which in the embodiment shown in Figure 1 comprises the low noise amplifier 28 and an unbalanced output coupled to the element PR3 of the PIFA 24. A series 1.5 nH inductor 72 and a shunt 2.4pF capacitor 74 are provided in the output circuit of the filter 24 and comprise the matching/frequency tuning network 25. The capacitor 74 increases the resonant frequency of the antenna and the inductor 72 ensures that the receiver side is matched and that the combination of the transmitter filter's static capacitance (not shown) and the external circuitry present an approximate short circuit to the antenna for the receiver.

Figure 5 shows the S_{11} response for the combined PIFA and filter combination shown in Figure 4 together with an idealised characteristic 84 shown by a chain-dot line for a broadband antenna operating over the UMTS band of frequencies. The S_{11} response comprises a transmitter characteristic 80 shown by a full line and a receiver characteristic 82 shown by a broken line. Referring to the transmitter characteristic 80 the points referenced r1 and r2 and respectively indicate an attenuation of -18.428 dB at a frequency of 1.920 GHz and an attenuation of -6.282 dB at a frequency of 1.980 GHz. In the case of the receiver characteristic 82 the points referenced r3 and r4 respectively indicate an attenuation of -14.057 dB at a frequency of 2.110 GHz and an attenuation of -13.471 dB at a frequency of 2.170 GHz.

It is evident that an acceptable performance is achieved in both the transmitter and receiver bands using an antenna that is too small to cover both bands simultaneously. In the combination shown in Figure 4 the receiver was optimised first and in consequence shows a better performance which is facilitated by the inherent better performance of the lattice filter 24. However it is believed that the transmitter performance could be improved by further design iterations.

Figure 5 confirms that the concept of utilising filters to make a compact antenna reusable at different frequency duplex frequencies is valid. It is

possible for similar results to be obtained with other types of filter besides BAW filters, such as SAW and ceramic filters.

In the present specification and claims the word "a" or "an" preceding an element does not exclude the presence of a plurality of such elements. Further, the word "comprising" does not exclude the presence of other elements or steps than those listed.

From reading the present disclosure, other modifications will be apparent to persons skilled in the art. Such modifications may involve other features which are already known in the design, manufacture and use of wireless terminals and component parts therefor and which may be used instead of or in addition to features already described herein. Although claims have been formulated in this application to particular combinations of features, it should be understood that the scope of the disclosure of the present application also includes any novel feature or any novel combination of features disclosed herein either explicitly or implicitly or any generalisation thereof, whether or not it relates to the same invention as presently claimed in any claim and whether or not it mitigates any or all of the same technical problems as does the present invention. The applicants hereby give notice that new claims may be formulated to such features and/or combinations of such features during the prosecution of the present application or of any further application derived therefrom.

CLAIMS

1. A wireless terminal for use in the transmitting and receiving frequency bands of a frequency duplex system, comprising transmitting and receiving stages and signal propagating means coupled to the transmitting and receiving stages, wherein the signal propagating means comprises an antenna structure having sufficient bandwidth to cover the larger one of the transmitting and receiving frequency bands, a receiving filter and a transmitting filter coupled by respective feeds to the antenna structure.

2. A terminal as claimed in claim 1, characterised in that the antenna structure comprises a Planar Inverted-F Antenna (PIFA).

3. A terminal as claimed in claim 2, characterised in that the PIFA includes two differential slots.

4. A terminal as claimed in claim 3, characterised in that the two differential slots separate the PIFA into a central element and two outer elements, the central and outer elements being interconnected, in that a free end of the central element is connected to a ground plane and in that free ends of the two outer elements are connected respectively to the receiver and transmitter filters.

5. A terminal as claimed in claim 3 or 4, characterised in that the differential slots are of substantially the same size and shape.

6. A terminal as claimed in claim 3 or 4, characterised in that the differential slots are asymmetric.

7. A terminal as claimed in any one of claims 1 to 6, characterised in that the transmitter and receiver filters are Bulk Acoustic Wave (BAW) filters.

8. A module for use in a wireless terminal operable in the transmitting and receiving frequency bands of a frequency duplex system, comprising signal propagating means including an antenna structure having sufficient bandwidth to cover the larger one of the transmitting and receiving
5 frequency bands, a receiving filter and a transmitting filter coupled by respective feeds to the antenna structure and having terminals for connection to the RF stages the wireless terminal.

9. A module as claimed in claim 8, characterised in that the antenna
10 structure comprises a Planar Inverted-F Antenna (PIFA).

10. A module as claimed in claim 9, characterised in that the PIFA includes two differential slots.

11. A module as claimed in claim 10, characterised in that the two
15 differential slots separate the PIFA into a central element and two outer elements, the central and outer elements being interconnected, in that a free end of the central element is connected to a ground plane and in that free ends of the two outer elements are connected respectively to the receiver and
20 transmitter filters.

12. A module as claimed in any one of claims 8 to 11, characterised in that the transmitter and receiver filters are Bulk Acoustic Wave (BAW) filters.

13. A wireless terminal constructed and arranged to operate
25 substantially as hereinbefore described with reference to and as shown in the accompanying drawings.

14. A module constructed and arranged to operate substantially as
30 hereinbefore described with reference to and as shown in the accompanying drawings.

ABSTRACT

IMPROVEMENTS IN OR RELATING TO WIRELESS TERMINALS

5 A wireless terminal for use in the transmitting and receiving frequency
bands of a frequency duplex system comprises transmitting and receiving
stages (Tx, Rx) and signal propagating means (22, 24, 26) coupled to the
transmitting and receiving stages. The signal propagating means comprises a
10 narrow band antenna structure (24), such as a Planar Inverted-F Antenna
(PIFA), having sufficient bandwidth to cover the larger one of the transmitting
and receiving frequency bands and a BAW receiving filter (26) and a BAW
transmitting filter (22) coupled by respective feeds to the antenna structure
(24). The filters (22, 26) enable the antenna structure to have a small volume
and be reusable at different FDD frequencies.
